

# ICOM 4215 Project 1 Fall 2010

## Processor Simulator

---

Today: October 22, 2010

Due date: November 12, 2010

Points: 100 points (Penalties: Next day: -10 points, Two days late: -25 points, Three days late: -40 points, Four days late or more: not accepted)

Group project – two students per group

Submission:

- Via oral exam, aka “Happy Hour”
- Report, via email

### Project

In order to understand how a processor works and the different aspects taken into consideration when designing a processor, we are requesting that you design a simulator for a simple processor. The following sections describe the processor.

### General Processor Description: RISC AR

The RISC 100AR is a processor designed by your professor, taking the ideas from the Simple Risc Processor, from the Jordan and Heuring textbook, a processor designed by Manuel Jimenez, Sunil Vaidya, Bradley Vansant, and Dave Dorner for the EE 813 graduate course at Michigan State University, and the processor designed by Adem Kader and Mustafa Paksoy for the E25 : COMPUTER ARCHITECTURE course at Swathmore University.

### Processor Features:

- 8-bit internal data bus
- Internal 256-word 8 bit wide program memory
- 8 byte register file
- On chip 4 bits hardware multiplier providing 8 bit results.
- 2 external I/O pins
- RISC instruction set: 20 instructions
  - 5 arithmetic
  - 3 logical
  - 5 data transfer
  - 6 control flow instructions
  - 1 machine control

## Processor Block Diagram

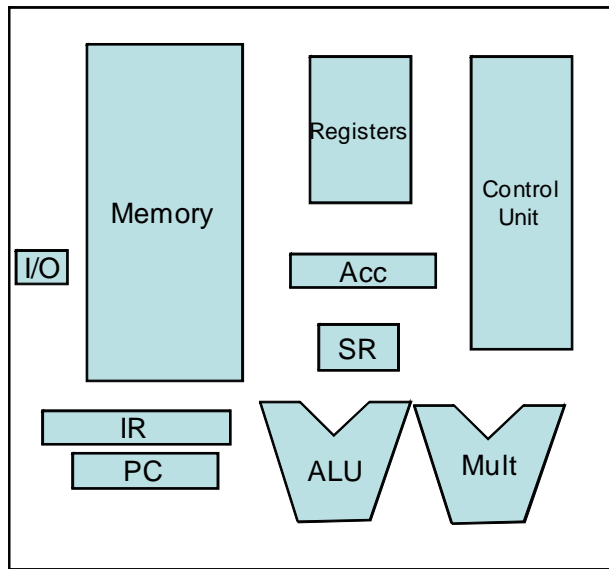

Figure 1: Block diagram of the RISC AR

## Memory and Registers

The size of the memory is 256 organized as 256 addresses of 1 byte each.

Figure 2: Visual illustration of the memory of the RISC AR

Internally, the processor has 8 general purpose registers, 8 bits each. The names of the registers are from **R0** to **R7**.

Figure 3: Visual illustration of the general purpose register structure of the RISC AR

The processor has a 8 bit program counter called **PC**, an 8 bit accumulator called **A**, and a 16 bit instruction register called **IR**. There is a 4-bit status register called **SR**. The format of the Status

Register is 

Z	C	N	O
---	---	---	---

 where Z is zero, C is Carry, N is negative, and O is overflow. When instructions are saved into memory, big endian ordering is used.

Four addressing modes are supported by the processor:

- a) Implicit
- b) Immediate
- c) Direct
- d) Register indirect

The list below shows the different addressing modes supported and the corresponding instruction formats for each (see figures 4 to 7).

(a) *Implicit addressing*: The only operand needed is contained in the accumulator (A)

Figure 4: Instruction format for the *Implicit* addressing mode

(b) *Immediate addressing*: The data to be operated is part of the instruction itself.

Figure 5: Instruction format for the *Immediate* addressing mode

(c) *Direct*: The memory location is indicated within the instruction

Figure 6: Instruction format for the *Direct* addressing mode

(c) *Register indirect*: Register f points to the memory location to be accessed.

Figure 7: Instruction format for the *Register Indirect* addressing mode

### Instruction Set

The following table is a summary of the instruction set of the RISC AR. Note that register f refers to one of the eight general purpose registers.

Table 1: Instruction set of the RISC AR

	Opcode	Name (Mnemonic)	Operands	Addressing Modes	Operation	Details
1	00 000	AND A, rf	Accumulator, register f	Direct	$A \leftarrow A \text{ and } rf$	Logical AND
2	00 001	OR A, rf	Accumulator, register f	Direct	$A \leftarrow A \text{ or } rf$	Logical OR
3	00 010	ADDC A, rf	Accumulator, register f	Direct	$A \leftarrow A + (rf) + \text{carry}$	Addition with carry
4	00 011	MUL A, rf	Four least significant bits of accumulator, four least significant bits of register f	Direct	$A \leftarrow A * (rf)$	Multiply
5	00 100	NEG A	Accumulator	Implicit	$A \leftarrow \text{not}(A)$	Two's complement
6	00 101	RLC A	Accumulator	Implicit	$A \leftarrow A6..A0 \ \& \ Cf, Cf \leftarrow A7$	Rotate left through carry
7	00 110	RRC A	Accumulator	Implicit	$A \leftarrow Cf \ \& \ A7..A1, Cf \leftarrow A0$	Rotate right through carry
8	00 111	DEC A	Accumulator	Implicit	$A \leftarrow A - 1$	Decrement accumulator
9	01 000	LDA rf	Accumulator, register f	Direct	$A \leftarrow (rf)$	Load accumulator from register f
10	01 001	STA rf	Accumulator, register f	Direct	$(rf) \leftarrow A$	Store accumulator to register f
11	01 010	LDA addr	Accumulator	Direct	$A \leftarrow [\text{addr}]$	Load accumulator from memory location addr
12	01 011	STA addr	Accumulator	Direct	$[\text{addr}] \leftarrow A$	Store

						accumulator to memory location addr
13	01 100	LDI Immediate	Accumulator	Immediate	$A \leftarrow \text{Immediate}$	Load accumulator with immediate
14	10 000	BRZ	Status register	Implicit	If Z=1, PC $\leftarrow r7$	Branch if Zero
15	10 001	BRC	Status register	Implicit	If C=1, PC $\leftarrow r7$	Branch if Carry
16	10 010	BRN	Status register	Implicit	If N=1, PC $\leftarrow r7$	Branch if Negative
17	10 011	BRO	Status register	Implicit	If O=1, PC $\leftarrow r7$	Branch if Overflow
18	10 101	BRA addr	PC	Direct	PC $\leftarrow \text{addr}$	Unconditional branch
29	11 000	NOP		Implicit		No operation
20	11 111	STOP	PC	Implicit		Stop execution

Arithmetic instructions use a 2's complement representation for negative numbers. This format is also used to compute memory addresses when accessing memory. Register 7 is a special register that will be used for branching conditions.

### Processor Configuration

The processor operates with instructions located in main memory from address 0 to address 127. When the processor starts, it will always do so from location 0 and 1.

The system will also have two devices connected to I/O ports using the following memory locations:

250-251: 16 bits, input from keyboard

252 – 255: Hex display, each byte will represent one digit

The information coming from the keyboard will be entered at the keyboard of the computer running the simulation. The hex display will be presented at the computer screen of the computer running the simulation. The data entered in the keyboard will have the corresponding ASCII value and the data written to the hex display should have the ASCII code for the corresponding character. The following figure illustrates a possible configuration of the graphical user interface for the simulator you will design.

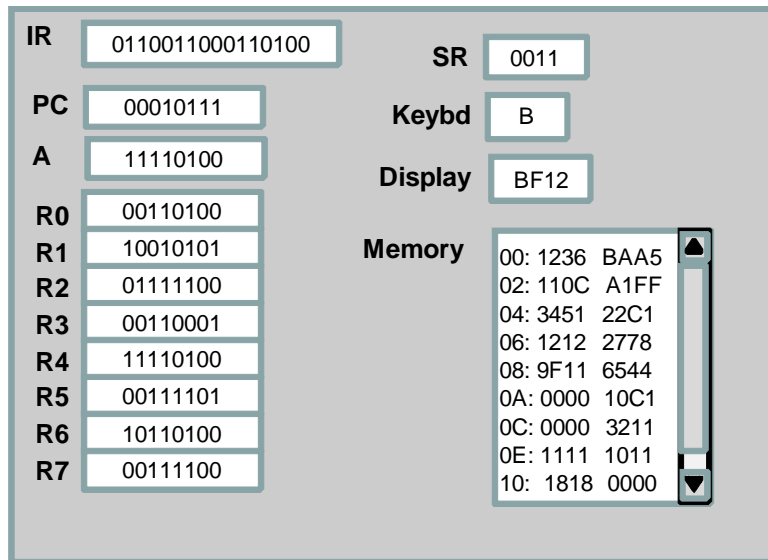

Figure 8: Possible graphical user interface arrangement

## Project requirements

### Simulator characteristics

The simulator must simulate all instructions in the instruction set, including all addressing modes. The simulator will run the instructions located in the main memory, starting with address zero (PC=0). The contents of memory are changed as a file with instructions is loaded into the simulator. Your professor will bring a simulation file on the oral exam day. This file will contain one line per instruction, and it will be represented in HEX characters (4 Hex characters).

The following example illustrates an input file:

```
2B00
2C00
1B82
6270
```

The simulator should run in two different modes: run or step. Run mode will allow programs to run from start to end. Step mode will run one instruction at a time. Please notice that the last instruction in any file should be stop. The simulator must show the contents of all registers, program counter, instruction register, and the contents of a section of memory. The directions in memory should be shown in HEX representation

Your design may use a graphical user interface or a plain text interface. Use any programming language of your preference.
